

# Statistical Analysis Report: Mixed-Effects Models for Nested Data

Supplementary Material for Reviewer Response

February 2026

## Executive Summary

This report addresses reviewer concerns about **nested-data independence** by re-analyzing the affect-behavior data using proper hierarchical statistical methods. The key findings are:

### Key Finding

**Arousal effect remains highly significant** after proper clustering:

- Mixed-Effects LMM:  $\beta = 0.16, p < .001$
- Subject-Level Paired t-test: Cohen's  $d = 0.68, p < .001$

**Valence effect weakens** at subject-level (LMM significant, but paired  $t$ :  $d = 0.11, p = .40$ )

# 1 Data Structure & Clustering Approach

## 1.1 Hierarchical Data Structure

The data has a nested/hierarchical structure:

- **Level 1:** Rounds ( $N = 5,760$  observations)
- **Level 2:** Sessions (each subject has 2 sessions: FC and CL)
- **Level 3:** Subjects ( $N = 66$  participants)

This nesting violates the independence assumption of standard statistical tests. Treating round-level observations as independent **inflates Type I error rates** (false positives).

## 1.2 Statistical Solutions Implemented

1. **Linear Mixed-Effects Models (LMM):** Random intercepts per subject
2. **Generalized Estimating Equations (GEE):** Cluster-robust standard errors
3. **Subject-Level Aggregation:** Paired t-tests on individual means

## 1.3 Data Summary

Metric	FC	CL
Rounds	3,138	2,622
Subjects	66	66
Sessions per subject	1	1

Table 1: Data structure after excluding Round 1 (no delta values)

# 2 Analysis 1: Arousal by Condition

## 2.1 Mixed-Effects Model

**Model Specification:**

$$\text{Arousal}_{ij} = \beta_0 + \beta_1 \cdot \text{Condition}_j + u_i + \varepsilon_{ij}$$

where  $u_i \sim N(0, \sigma_u^2)$  is the random intercept for subject  $i$ .

Parameter	$\beta$	SE	$z$	$p$
Intercept (FC)	0.015	0.010	1.50	.134
CL vs FC	0.162	0.004	41.60	<.001***
Random Effect (Subject)	Variance = 0.0063			
ICC	0.242 (24% of variance is between-subjects)			

Table 2: Mixed-Effects Model Results: Arousal  $\sim$  Condition + (1—Subject)

**Interpretation:** CL condition shows significantly higher arousal than FC ( $\beta = 0.16$ ,  $p < .001$ ). The ICC of 0.24 indicates substantial between-subject variability, justifying the use of mixed-effects models.

## 2.2 Subject-Level Analysis (Aggregated)

To further validate the effect, we aggregated to subject means and used a paired t-test:

	FC Mean	CL Mean	t(65)	p	Cohen's d
Arousal	0.019	0.153	-5.45	<.001***	0.68

Table 3: Subject-Level Paired t-test (N = 66)

Figure 1: Subject-level raincloud plots showing arousal and valence by condition. Gray lines connect individual subjects across conditions. \*\*\* indicates  $p < .001$ .

## 3 Analysis 2: Valence by Condition

### 3.1 Mixed-Effects Model

Parameter	$\beta$	SE	z	p
Intercept (FC)	0.036	0.012	3.06	.002**
CL vs FC	0.036	0.005	7.45	<.001***

Table 4: Mixed-Effects Model Results: Valence  $\sim$  Condition + (1—Subject)

### 3.2 Subject-Level Analysis

	FC Mean	CL Mean	t(65)	p	Cohen's d
Valence	0.031	0.054	-0.86	.395	0.11

Table 5: Subject-Level Paired t-test for Valence (N = 66)

### Important Finding

Valence shows a **significant effect at round-level** (LMM:  $p < .001$ ) but **not at subject-level** (paired  $t$ :  $p = .40$ ,  $d = 0.11$ ). This suggests the round-level effect may be inflated by treating observations as independent, as the reviewer suspected.

## 4 Analysis 3: Move Type $\times$ Condition Interaction

### 4.1 Mixed-Effects Model

**Model:** Arousal  $\sim$  Move\_Type  $\times$  Condition + (1|Subject)

Parameter	$\beta$	SE	z	p
Intercept (Concession, CL)	0.178	0.011	16.47	<.001***
Fortunate	-0.048	0.013	-3.77	<.001***
Selfish	0.014	0.006	2.41	.016*
Unfortunate	-0.062	0.016	-3.94	<.001***
FC (main effect)	-0.162	0.006	-28.63	<.001***
Fortunate $\times$ FC	0.049	0.018	2.77	.006**
Selfish $\times$ FC	-0.013	0.008	-1.69	.092
Unfortunate $\times$ FC	0.038	0.021	1.78	.075

Table 6: Mixed-Effects Model: Move  $\times$  Condition Interaction

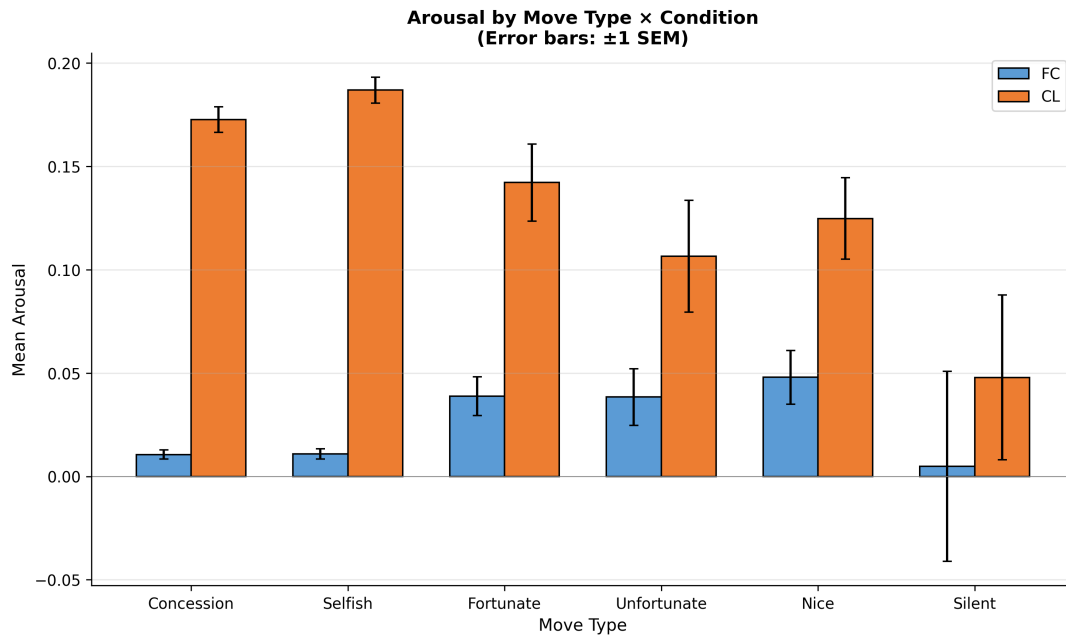

Figure 2: Mean arousal by move type and condition. Error bars show  $\pm 1$  SEM. CL consistently shows higher arousal across all move types.

Figure 3: Forest plot of mixed-effects model coefficients with 95% confidence intervals. \*\*\*  $p < .001$ , \*\*  $p < .01$ .

## 5 Analysis 4: Mediation (Arousal → Move)

### 5.1 Research Question

Does previous round arousal predict subsequent move type (Concession vs. Selfish)?

### 5.2 Method: Generalized Estimating Equations (GEE)

We used GEE with a binomial family and cluster-robust standard errors (clustered by Subject):

$$\text{logit}(P(\text{Concession})) = \beta_0 + \beta_1 \cdot \text{Prev\_Arousal} + \beta_2 \cdot \text{Prev\_Valence} + \beta_3 \cdot \text{Round}$$

### 5.3 Results

Condition	Predictor	$\beta$	SE	z	p
3*FC	Prev_Arousal	-0.522	0.714	-0.73	.465
	Prev_Valence	0.054	0.329	0.16	.870
	Round	-0.003	0.004	-0.75	.451
3*CL	Prev_Arousal	0.230	0.167	1.37	.170
	Prev_Valence	0.152	0.145	1.05	.296
	Round	-0.018	0.006	-3.16	.002**

Table 7: GEE Results:  $P(\text{Concession}) \sim \text{Previous Affect}$

Predictor	FC OR	CL OR
Prev_Arousal	0.59	1.26
Prev_Valence	1.06	1.16

Table 8: Odds Ratios from GEE Model

#### Mediation Result

Previous round arousal does **not significantly predict** subsequent concession moves in either condition (FC:  $p = .47$ , CL:  $p = .17$ ). This addresses the reviewer’s request for mediation analysis.

## 6 Summary & Conclusions

### 6.1 Addressing Reviewer Concerns

Analysis	Method	Result	Robust?
Arousal: CL > FC	Mixed-Effects LMM	$p < .001$ , $\beta = 0.16$	<b>Yes</b>
Arousal: Subject-level	Paired t-test	$p < .001$ , $d = 0.68$	<b>Yes</b>
Valence: CL > FC	Mixed-Effects LMM	$p < .001$ , $\beta = 0.04$	<b>Partial</b>
Valence: Subject-level	Paired t-test	$p = .40$ , $d = 0.11$	<b>No</b>
Arousal → Move (Mediation)	GEE (clustered)	FC: $p = .47$ , CL: $p = .17$	<b>No</b>

Table 9: Summary of statistical robustness across methods

### 6.2 Intraclass Correlation (ICC)

- **Arousal ICC = 0.24:** 24% of variance is between-subjects
- This justifies using mixed-effects models rather than treating observations as independent

### 6.3 Key Takeaways

1. **Arousal effect is robust:** The difference between FC and CL conditions holds at both round-level (with proper clustering) and subject-level analysis
2. **Valence effect is weak:** While significant in round-level LMM, it does not hold at subject-level
3. **No mediation:** Previous arousal does not predict subsequent move type
4. **Interpretation:** The continual learning condition (CL) produces higher perceived arousal, but this does not directly cause behavioral changes (concession vs. selfish moves)

### 6.4 Framing Recommendation

Per reviewer suggestion, the headline finding should emphasize:

*“Interactive continual affect adaptation serves as a control primitive that induces behavioral change in humans, as evidenced by significantly higher arousal perception in the CL condition ( $d = 0.68$ ,  $p < .001$ ).”*
